

# Lab 5 Instructions, Arrays, Group A

## CS 133JS, Beginning Programming: JavaScript

### Overview

The objective of this lab is to give you practice using:

- Creating an array
- Adding values to an array
- Getting values from an array
- Calling array methods to do special operations on the array

### Part 1: Array Exercises

A web page, *ArrayExercises.html*, has been written for you that contains code to call functions that you will write in a file named *ArrayExercises.js*. The instructions for writing your functions and the code to test your functions are in *ArrayExercises.html*, but all the code you write will go in *ArrayExercises.js*.

Here is a screenshot of the finished ArrayExercises web page:

## Lab 5, Part 1: Array Exercises

For each of the problems below, create an array, or write a function in a file named *ArrayExercises.js*. This web page contains code to test your solution code.

### Basic Array Operations

1. Declare an array named *degrees*, but don't initialize it.
2. Write a function named *addDegree* that takes a degree name as a parameter and adds it to the *degrees* array. Here is a listing of the array:

0, Network Operations

1, Cybersecurity

2, Computer Programming

3, Game Development

4, ASOT CS
3. Write a function that lets you change the name of a degree by index. We'll change the name of Computer Programming to Software Development. The degree with index 2 is named: Software Development

### Using Arrays in Loops

1. Write a special function named *copyDegrees* to create a copy of the global *degrees* array. It should take no parameters, just return a new array. To demonstrate we'll create a new array named *programs* and we'll change the name of the third degree back to "Computer Programming". In *degrees*, the third degree is: Computer Programming. In *programs*, the third degree is: Software Development
2. Write a function named *countMatches*, that takes two parameters, compares two arrays, and sreturn the number of elements with matching values. We will compare the two arrays above. There should be 4 elements that contain the same values. Number of matches: 4

### Working with 2D Arrays

1. Declare an array named *checkers* to represent a checker board. Don't initialize it. The checkers array has been initialized with 64 squares.
2. Write a function to display the board (it will return a string with the HTML that represents the board.) The board:

BRBRBRBR

RBRBRBRB

BRBRBRBR

RBRBRBRB

BRBRBRBR

RBRBRBRB

BRBRBRBR

RBRBRBRB
3. Write a function named *makeMove* to place a Red or Black checker on the board. Your function will take these parameters: row, column, letter. We'll use lower case letters to represent the checkers and just put 4 checkers on the board. Checker board:

bRbRBRBR

RBRBRBRB

BRBRBRBR

RBRBRBRB

BRBRBRBR

RBRBRBRB

BRBRBRBR

RBRBRBRB

### Part 2: Web Apps

You will create two web apps. The HTML page for each of these has already been written for you. You will just write the JavaScript file.

#### Web App I for Group A – Roman Numeral Converter

Write a function named *romanToDecimal* that will convert a Roman numeral to a decimal number.

The function will:

- Have one parameter, a Roman numeral (a string).
- Return one value, a decimal number (a number).
- Work for Roman numerals I through X.
- Use an array containing hard-coded values to convert the Roman numeral to a decimal number.

Here is a screenshot of the finished web app:

## Roman Numeral Calculator

 

Roman numeral VII is equal to decimal 7

CS 133JS, Beginning Programming: JavaScript

### Web App II for Group A – Grade Book

This web app displays a list of students and allows an instructor to add names to the list and enter grades. Here are the implementation instructions:

1. Declare two one-dimensional global arrays:
  - a. *students*
  - b. *grades*
2. Write three functions:
  - a. *addStudent*
    - Has one parameter: a student's name.
    - Adds an element with the student's name to the *students* array and puts an element in the *grades* array with a default grade value.
  - b. *removeStudent*, this function:
    - Has one parameter: the array index for the student.
    - Returns true if the index is valid.
    - Hint: Use the *splice* method to remove the student and the grade from the arrays.
  - c. *changeGrade*
    - Has two parameters: student's name, grade.
    - Returns true if the student's name was found.
    - Use the *indexOf* method to get an index, then change the value in the grades array.

This is a screenshot of a working Grade Book web app:

### Grade Book

Student			Grade	
1	Lucy Pevensie	Delete	A	<input type="text" value="A"/> Enter
2	Jill Pole	Delete	B+	<input type="text" value="B+"/> Enter
3	Eustace Scrubb	Delete	B	<input type="text" value="B"/> Enter
4	Edmond Pevensie	Delete	A-	<input type="text" value="A-"/> Enter
5	Polly Plumber	Delete	U	<input type="text"/> Enter
<input type="text" value="Polly Plumber"/>			Add Student

### Submitting your lab work on Moodle

#### Beta Version

Post the following in the *Lab Beta forum*:

1. The web pages you created for part 2.  
(Zip the files for your web pages and attach them to the post.)
2. A code review of your lab partner's web page for part 2.  
(Review the part 2 web apps for one of your lab partners using the Code Review Form provided.)

#### Code Review

1. Submit a copy of the code review above to the *Lab Code Review assignment*.

#### Production Version

You may revise your beta version before submitting the production version. On the code review form you received from your lab partner, complete the "Production" column to show what you did or did not revise.

Upload the following 7 files to the *Lab Production Version* assignment:

1. Two files (.html and .js) for part 1.
2. Four files (2 html and 2 js) for part 2.
3. The code review from your lab partner with the "Prod" column filled in by you.
